# 3CW Cottonwood Project Report for CWSP and Kootenay Connect-2021-2022

By

## **Kyle Prince, Suzanne Bayley and Annie Pankovitch**

March 31, 2022

Environnement et Changement climatique Canada

#### 3CW Cottonwoods: Monitor and mitigate impact of beaver on cottonwood/aspen stands

The purpose of the cottonwood/beaver project is to assess the status of important cottonwood stands and install wire protectors if they are required to protect critical stands from beaver harvesting. If feasible, start to assess the regeneration of cottonwood on the levees. This subproject used the wetland mapping from Yr1 to identify the stands of cottonwoods, used a survey of important wildlife cottonwood trees to identify critical trees and small stands, and then after seeking permission of selected landowners, installed wire around selected cottonwood trees. In total 45 large trees, often near active beaver colonies were protected. The project brought in a Youth Climate Corp to assist with the installation of the wire.

**Work plan**: 1. Assess the status of wire guards put on in previous years to protect cottonwood- did they protect the trees?

The CWSP team assessed one stand that had had historic wire guards in place, the wire appeared to be very effective at protecting cottonwood stand. There is one other stand in Columbia Wetlands which we know able but were unable to access due to high water.

#### **Examples:**

- <u>Davdison Marsh</u>-Near Parson, a private landowner has approximately 25 cottonwoods wired near their yard alongside a large wetland complex. This appeared to be very effective and has halted any major cottonwood damage or harvest despite the thriving beaver population in the adjacent wetland. They used chicken wire which is often discouraged as it can rust away however, in their case it appears to be effective.
- 2. Locate the large stands of cottonwoods & aspens in CW using the CWSP wetland mapping and LiDAR from Yr 1. This requires locating mature stands with structural stage attributes and software script with the LiDAR to determine the density and height of the forests.

CWSP LiDAR mapping from Yr 1 was used to locate areas with important cottonwood stands in the Columbia wetlands from Invermere to Golden. Georeferenced maps of the cottonwood stands made on ArcGIS Pro 2.8.0 were used while locating cottonwood stands in the field.

#### **Examples:**

- See Appendix D for maps of cottonwood stands.
- 3. Visit the most important sites to assess the status of beaver damage.

Cottonwood Stand Surveys occurred in partnership with Living Lakes Canada over several days to investigate as many stands as possible along different stretches of the Columbia River. The team completed surveys via canoe on the following stretches:

Invermere to Radium (16km), Radium to Brisco (29km), Brisco to Spllimacheen (main channel-

15km and Bott's channel-7km), and Nicholson to Golden (10km), totalling in approximately 77 km surveyed.

The surveyors tracked the following information for each survey stretch at sites where significant cottonwood presence was observed using the CWSP wetland mapping and LiDAR from Yr 1. as a reference:

- time
- location (GPS waypoint)
- side of the river
- snag class (using BC's wildlife tree classification system-native broad leaved deciduous trees)
- observed wildlife use (cavities, nests, perching or notable bird species sighted)
- access note (poor, moderate, good-river or road)
- beaver activity (type and proximity)
- Other (Stand size, circumference, additional notes)

This information was collected from canoe, often while still floating by to cover the area in good time. Periodically surveyors would go to shore to measure some of the trees and check for beaver activity or damage to cottonwoods. The completed datasheets can be found in Appendix A.

Additionally, incidental information was tracked and collected while conducting other CWSP field work throughout the Columbia Wetlands and while engaging with landowners throughout the field season.

4. Locate where to install wire guards on large trees in important stands of aspen/cottonwood.

Once surveys were completed the CWSP team was able to compare significant cottonwood sites observed, beaver activity level, and access to determine multiple candidate stands for wire guard application. Access was deemed a significant factor to ensure that team members could safely get to selected stands with all the equipment needed to apply wire guards. It was also considered to facilitate easy follow up visits and maintenance over the following years. Beaver activity was also considered an important factor to determine where wire guard application should occur.

5. In winter 2021-2022, install wire protectors in most critical cottonwood stands

In November of 2021 wire guards were successfully installed at 4 different stands, with a total of 45 cottonwood trees.

- Methods and Materials: Heavy stucco wire (16 gauge) 4 feet tall, with 2"x 2" spaced mesh was installed around moderately mature cottonwood trees throughout selected stands. Approximately a 4" space was left between the tree and the wire to allow for growth and keep beavers from chewing between wire squares. Wire was secured together using rebarties, and to the ground using stakes made from nearby shrubs.
- <u>Installation Crew:</u> The wire was installed over several days by the CWSP team, Living Lakes
  Canada staff, and 6 crew members from Wildsight's Youth Climate Corps (YCC). The
  involvement of the YCC crew was an excellent addition to the project, providing them with

hands-on learning, and this project with significant in-kind contributions and overall cost reductions. CWSP hopes to continue working with LLC, and Wildsight's YCC for support with labour intensive projects.

• <u>Site Details:</u> The wire guards were applied at the following sites (see Appendix D, Map 6).

Site Name	Notes
Spillimacheen Bridge	<ul> <li>11 trees had wire guards applied.</li> <li>Access was good, right next to the road.</li> <li>Beaver activity was moderate. Lodge nearby, but no recent damage to any cottonwoods. Historic cuts and felling were minimal.</li> <li>Average tree circumference was 1.69m</li> </ul>
Brisco area	<ul> <li>11 trees had wire guards applied.</li> <li>Access was moderate, 1km walk from the road.</li> <li>Beaver activity was high. Lodge nearby, historic cuts and felling. Recent feeding on small woody debris nearby</li> <li>Average tree circumference was 1.70m</li> </ul>
Beaver Dam Analogue- Brisco site	<ul> <li>7 trees had wire guards applied.</li> <li>Access was poor, quad access ¾ of the way or long hike.</li> <li>Beaver activity was high. Lodge nearby, and BDA constructed nearby. A few historic cuts on trees.</li> <li>Average tree circumference was 1.69m</li> </ul>
Radium	<ul> <li>16 trees had wire guards applied.</li> <li>Access was good, able to walk from the road.</li> <li>Beaver activity was high. Historic cuts and felling, along with multiple lodges nearby.</li> <li>Average tree circumference was 1.49m</li> </ul>

6. If feasible, bring in Stewart Rood to access the status of cottonwood and popular rejuvenation along the levees. Yr 4 will continue the installation of wire guards on mature cottonwood trees, especially the wildlife trees.

Dr. Stewart Rood, Canada's preeminent expert on cottonwood, was able to join CWSP on one of the survey routes earlier in the field season (July 2021) to provide a coarse assessment of overall cottonwood stand health, and rejuvenation. He visually determined that most stands were in good condition, especially near large alluvial fans where significant substrate is moved and deposited. The undammed nature of the Upper Columbia River and its tributaries appears to provide ideal conditions for Cottonwood health and regeneration increasing their value. This makes the Columbia Wetlands

especially valuable considering many Interior BC floodplains have been flooded or altered by human dams which radically alter the hydroperiod reducing the viability of cottonwoods. Dr. Rood determined that the Columbia Wetlands has healthy populations of cottonwoods but that most of the natural levees were not ideal for regenerating cottonwoods, as the sediment is too fine. That makes the good cottonwood stands located on the alluvial fans even more valuable, and important to protect. It also makes the few large cottonwoods on the natural levees very important for nesting eagles, ospreys and other birds. Another good feature that Dr. Rood noted was that cattle grazing in the floodplain in minimal, again another important cause of damage elsewhere. However, given the fine sediment on the levees, the few large remaining trees on the levees are important to protect. In year 4, after the fledging of the eagles and ospreys, we will install wire on selected wildlife trees.

#### Measurable outcomes

1. Map & assess the success of previous wire guards in protecting from beaver harvesting on aspen/cottonwoods in CW

See above

2. Map of large and important cottonwood/aspen stands in CW, especially those that contain SAR and concern.

See above

3. Assess the status of beaver damage on important cottonwood stands

Beaver damage was assessed while completing the cottonwood stand surveys, where beaver activity noted during (feeding sites, lodges etc.) which helped determine which stands were a priority and at risk of being damaged or felled. Additionally, more intensive surveys were completed near each of the 4 wire guard application sites to confirm beaver presence, and document historic damage/felling with GPS locations and photos.

Beaver activity was rated high in 3 of out 4 wire guard application sites due to the presence of close proximity lodges, active feeding signs along banks, and varying density of relatively recent cottonwood damage and felling.

4. Map locations where wire protectors will be installed on important cottonwood stands

Map of wire guard locations

- Shared Google Drive folder with KML and GPX files for wiring locations.
   2021 wireapplication GPXandKMLfiles
- Install wire protectors in at least 3 stands of cottonwood/aspens in winter 2021.

Completed. We explained the partnership with YCC, engaged youth etc. and described the selected locations and amounts, and tree size, along with beaver activity.

As noted in the work plan section 5 above, wire protectors were installed at 4 different stands on a

total of 45 trees in November 2021. This increased effort was made possible by a partnership with Living Lakes Canada (LLC) team members, and Wildsight's Youth Climate Corp team. The YYC crew was made up of 6 individuals between 20-30 years old, working on various projects in the East Kootenays to gain environmental experience and training with a focus on projects related to climate mitigation. LLC team members worked with the crew for 2 weeks providing training in various water quality and quantify monitoring protocols before helping with this project. The crew was able to help perform some maintenance on the Beaver Dam Analogue in the area, and then spent 2 ½ days assisting with wire guard application and beaver activity surveys. This partnership was extremely successful, provided a significant in-kind benefit to the project, and CWSP looks forward to continuing working with LLC and YYC team members moving forward.

# **List of Appendices:**

Appendix A. Cottonwood Stand Survey, and Wire Guard Application Datasheets	7
Appendix B. BC's wildlife tree classification system-native broad leaved deciduous trees	10
Appendix C. Photos during cottonwood field surveys	11
Appendix D. Maps	14

## Appendix A. Cottonwood Stand Survey, and Wire Guard Application Datasheets

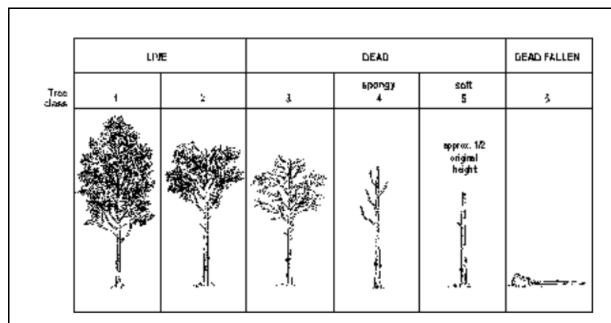

CWSP Cottonwood Stand Survey Data 2021			
Notes on Data Collection			
Data was collected via canoe.			
Photos were taken at almost all sites.			
Periodic stops on river banks were made to measure tree circumference.			
nag class was determined based on using BC's wildlife tree classification system	-native broad lea	ved deciduous tr	ees)
all significant wildlife sightings and use of trees were recorded (cavities, nests, per	ching or notable	bird species sigh	ted)
Access notes were taken to quickly capture feasibility of returning to access the stand. Poor indicates opposite side of river bank from highway, or far from river bank. Moderate, river- indicates easily accessed via canoe. Good indicates road or bridge.			
Beaver activity and close proximity to trees were noted.			
Other (Stand size, circumference, additional notes)
